Introduction

Research about explanation processes is gaining relevance because of the increased popularity of artificial systems required to explain their function or outcome. To make technology accessible is the goal of Explainable Artificial Intelligence (XAI) that develops models capable of explaining their functions. Current approaches in XAI allow the user to steer an explanation by asking questions [1], thus, allowing to personalize the interaction. However, although they build on the users’ ability to ask questions, they currently lack an empirical basis.

Research from human–human interactions following an interactive approach, has emphasized that not only explainers but also explainees contribute to successful interactions [1]. However, little is known about how explainees actively guide explanation processes within the ongoing interaction and how their involvement relates to learning.

Research Question

Little is known about how explainees in human–human interactions ask questions. Tutoring research found that explaining in form of long and monological statements only contribute little to learning [2]. Instead, requiring the active involvement of both participants contributed considerably to deep learning effects (see [3] for a summary). Our question is therefore what type of questions can an explainee ask to steer their own knowledge gap and learning.

Method

Participants were 40 native English-speaking students (mean age of 25 years) observed in dyadic explanation dialogues, i.e. 20 dyads were considered (5 female-female, 4 male-male, 11 female-male). These dialogues are part of the ECOLANG Corpus [4].

Stimuli

For each dyad, 24 stimuli objects (12 unknown, 12 known) out of a total of 36 objects were chosen. These objects belonged to four categories: tools, musical instruments, food, and animals (see Figure 1).

Coding Schema of Question Types

The questions were coded into six categories and transcribed using ELAN (2021) [5]. The categories are mainly based on the ones presented in Tare and colleagues (2011) [8] with some adjustments of the labeling and procedure questions.

<table>
<thead>
<tr>
<th>Question Type</th>
<th>Definition</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>Target the name of a stimuli in an oral or orthographic form.</td>
<td>What is that? How do you spell that? What’s it called okapi?</td>
</tr>
<tr>
<td>function</td>
<td>Different functions of a music instrument, tool or body parts of an animal and what they do. How to eat a fruit.</td>
<td>What does that do? And you eat it, like, with a spoon or something?</td>
</tr>
<tr>
<td>factual</td>
<td>Seek information of a profile or product description. Include general demands for more information and examples.</td>
<td>What’s a gourd? Where do they live? When was it invented? And then? Like a necklace not a brooch?</td>
</tr>
<tr>
<td>reassurance</td>
<td>Make sure the speaker is serious, a sign of disbelief or surprise or auditory difficulties.</td>
<td>Really? Shells, right? Is it?</td>
</tr>
<tr>
<td>procedure</td>
<td>Is an off-topic remark on how to continue with the discussion. Also includes information on the pre-session of the explainer.</td>
<td>Can I try? Did you watch videos? Well, they not told you?</td>
</tr>
<tr>
<td>personal</td>
<td>Includes individual preferences and experiences of the explainer and explainee.</td>
<td>Have you played it before? Did you know that yourself?</td>
</tr>
</tbody>
</table>

Results

Questions: All EEs engaged in asking questions. On average, EEs asked 29 questions (SD = 15.9, range 9–73). Factual and labeling questions were the most frequent ones in both conditions (present/absent). The object-present condition (M = 2.95, SD = 3.5) elicited more function questions than the absent condition (M = 1.05, SD = 1.2), Z = −2.46, p < .05. The other question types did not significantly differ between conditions.

Discussion

We found that EEs asked different types of questions, especially about the object’s label and facts. The labeling questions were linked to better recall. In general, the presence of an object does not seem to trigger a better or different involvement of the EE, except for function questions, which were asked more when objects were present. This suggests that the physical presence of the objects rendered their function-affording properties more saliently. The results contribute to designing XAI: To provide relevant explanations it is crucial to involve the user/EE and to base the explanations on the users’ questions.
